Pavement Management Today

- Pavement Management has been shifting in focus from capital investment in new projects to the enhanced management and preservation of existing assets.
- The health of road networks are significantly and positively impacted by advanced Pavement Management Systems that optimize and simplify the management of road networks, including optimization of treatments and resource allocation.

Case Studies

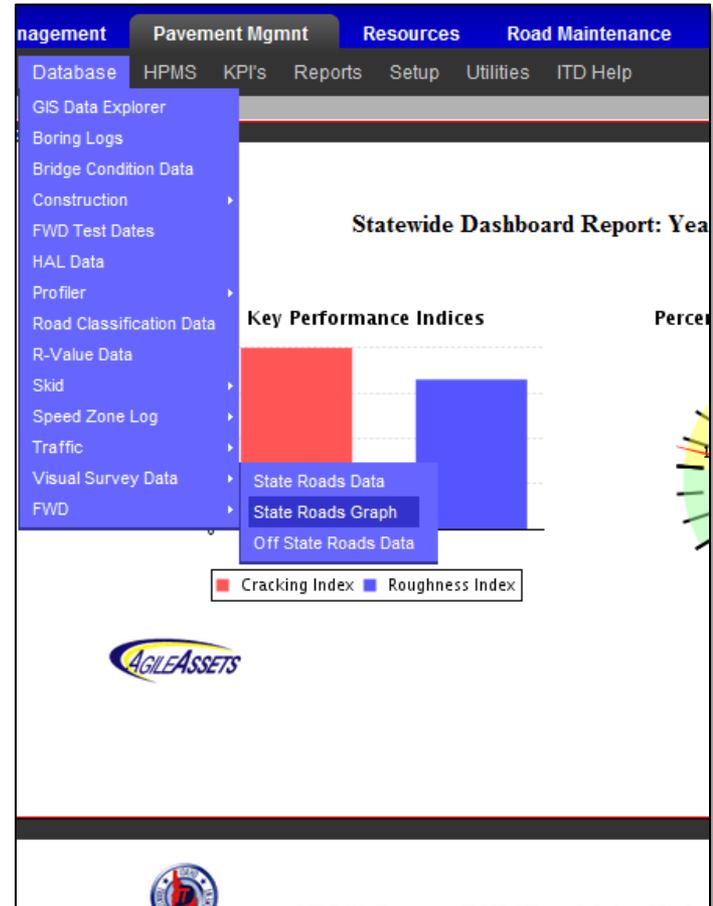

Advanced PMS Features

- 100% web-based application, zero footprint
- User-configurable database structure
- User-configurable models and calculations
- Multi-year & Multi-constraint Integer Optimization
- User-definable analysis variables
- Analytical performance modeling function

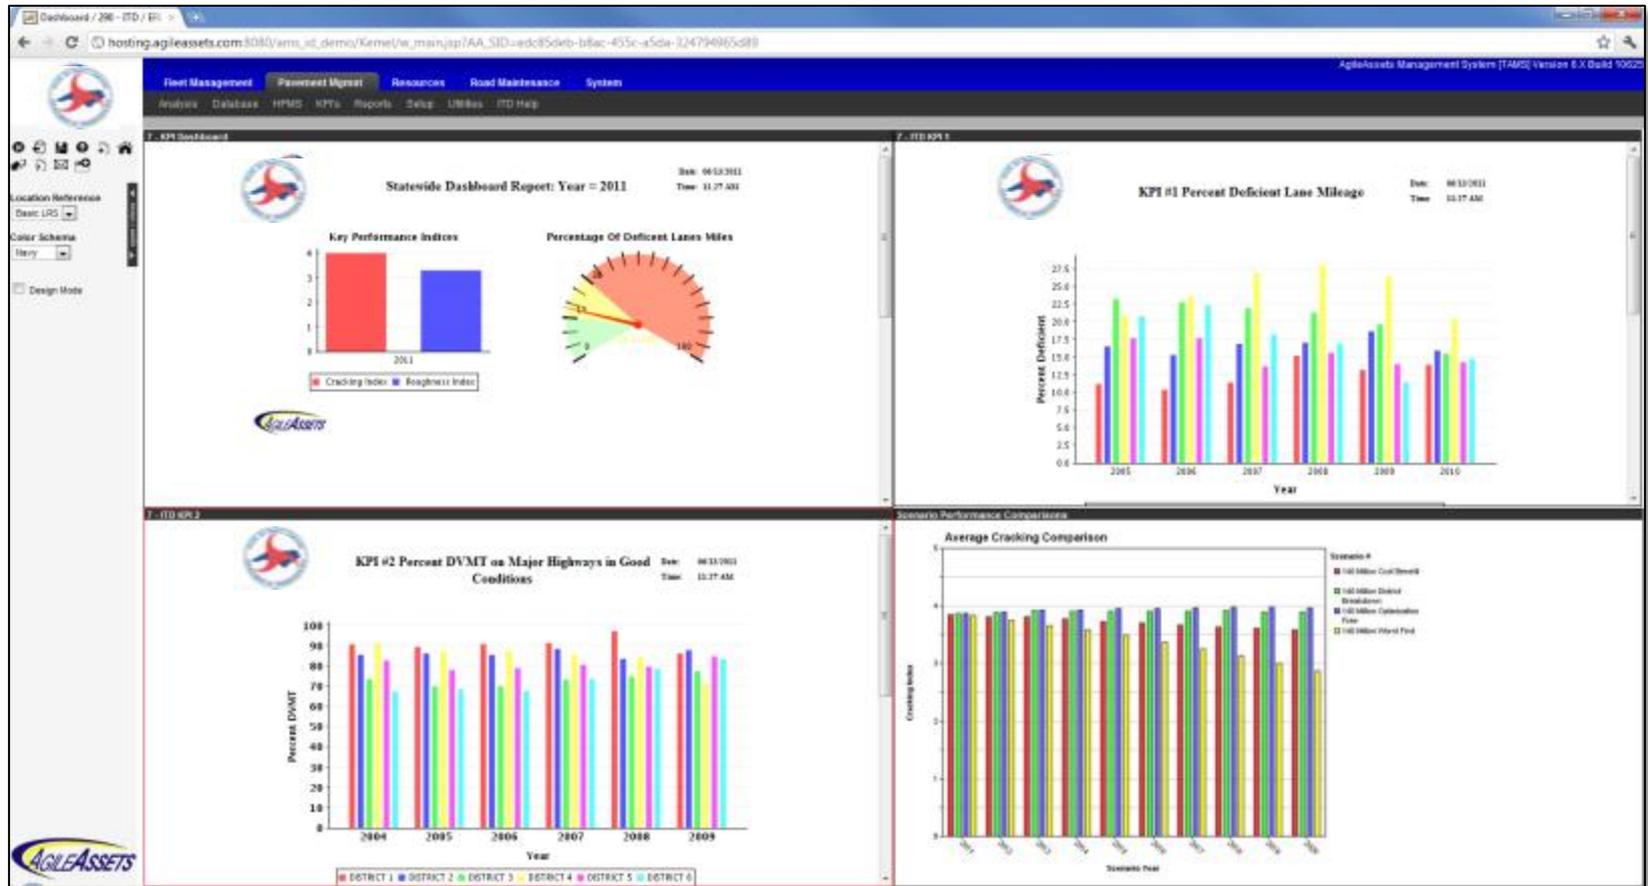

Database Menu and Configuration

- Database contains client data sources
- Fully front-end configured
- No required tables
- No generic fields

General Layout

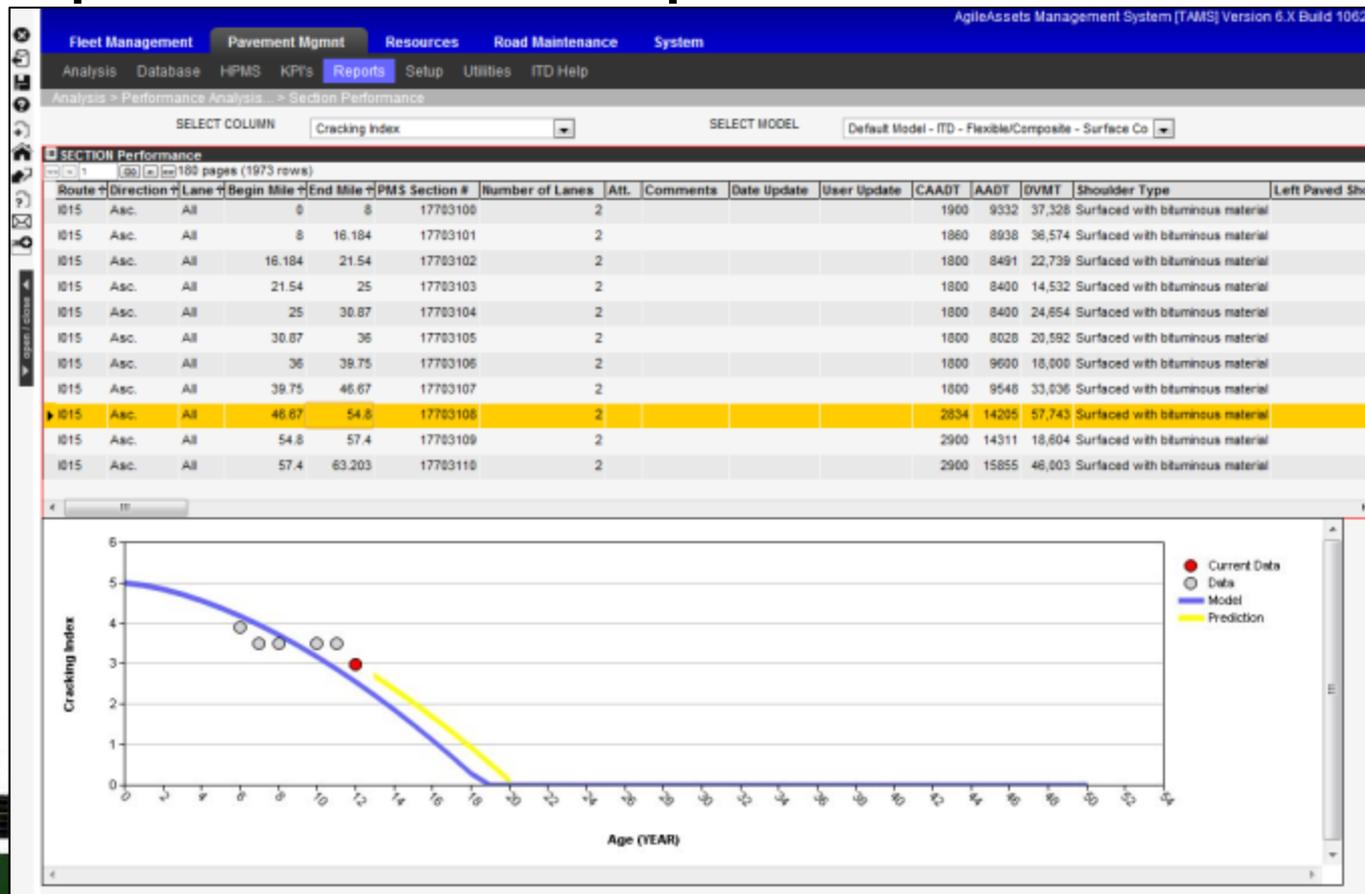

Pavement Life Extension with PMS

- How can pavement life extension be measured with PMS? With respect to modeling, how can PMS software be used to show how a preservation treatment would actually extend the life of the underlying pavement.

Pavement Life Extension with PMS

- Quebec uses Pavement performance monitoring analysis - Section performance compared to model prediction

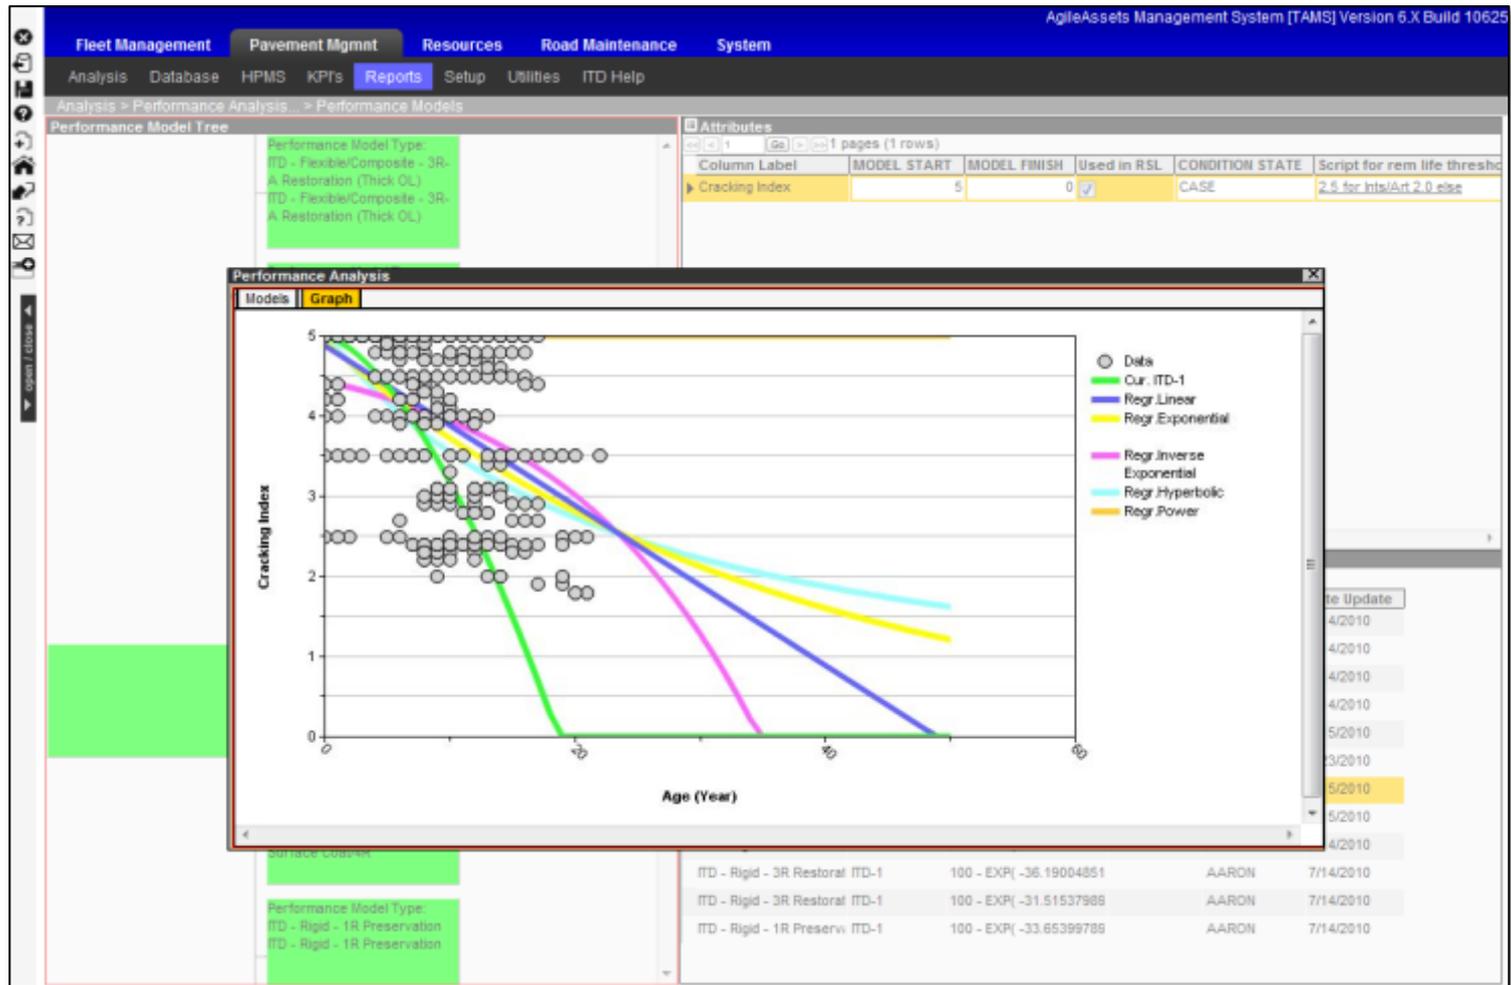

Pavement Life Extension with PMS

- VDOT PMS stores all condition data and treatment history.
- Extrapolated deterioration curves of sections prior to treatment can be compared to actual deterioration after the treatment to draw conclusions on the pavement life extension of preservation treatments.
- These comparisons can be performed on a section by section basis or on the network level.

Family Models

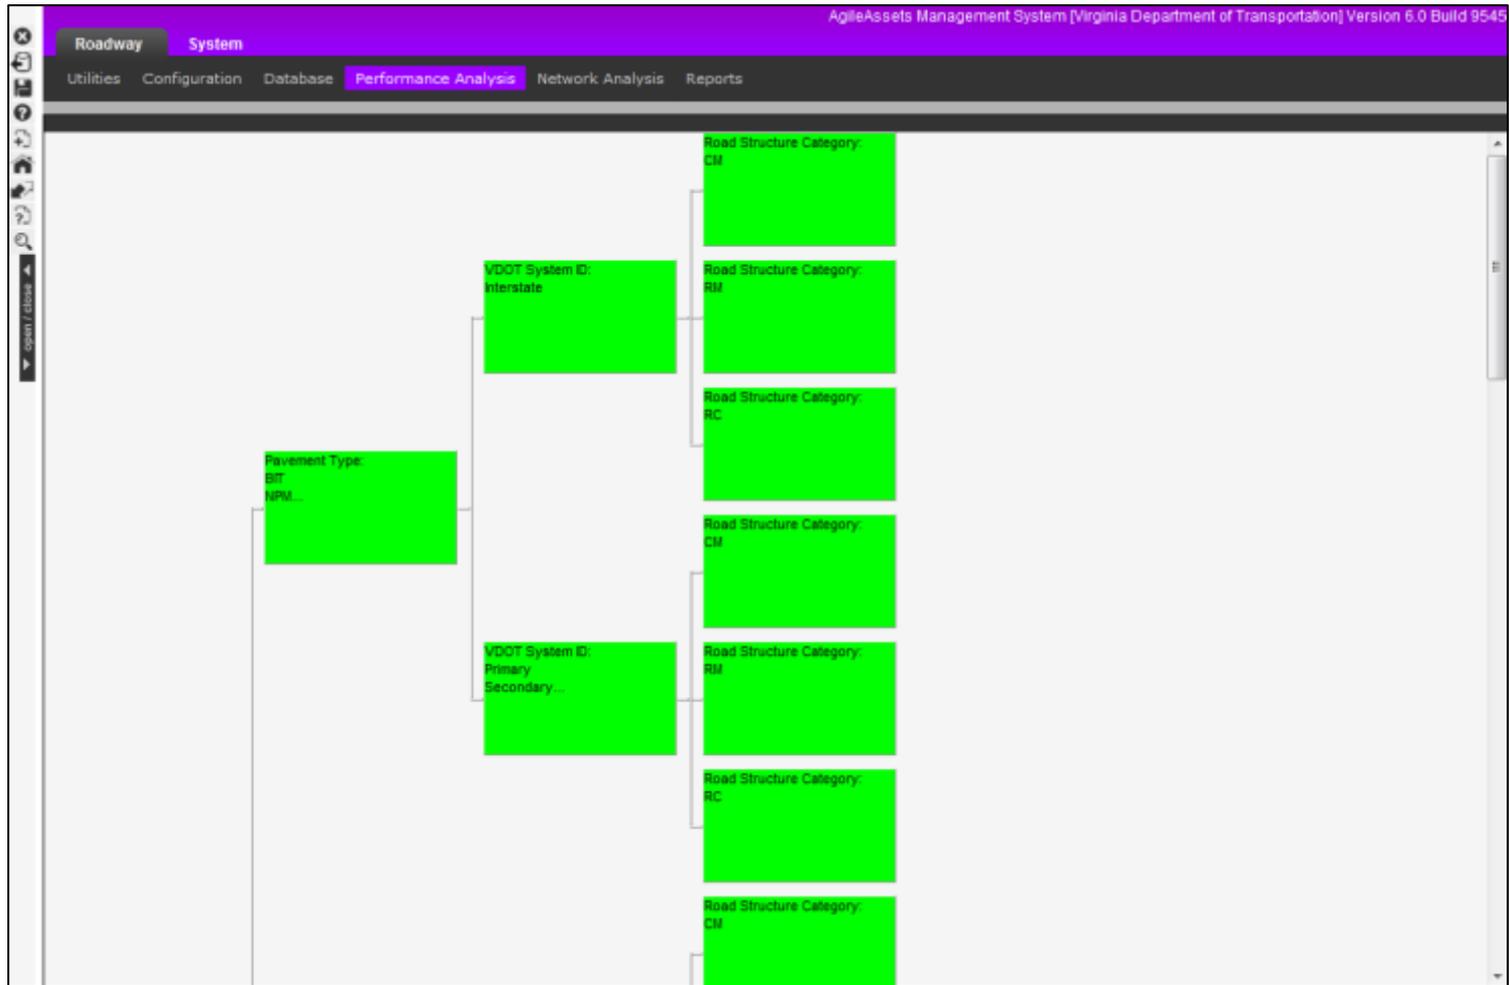

Pavement Life Extension with PMS

- NCDOT uses the section performance window to try to get a handle on the degree to which pavement treatments extend life.
- Also, they use the PMS as a convenient storage system so that condition and treatment data can be easily cross-referenced and they can analyze the data

Modeling Family Definition

Automated vs. Manual Data Collection

- Identify the pros and cons of automated data collection versus “windshield” data collection.

Automated vs. Manual Data Collection

- Automated data collection for IRI, rutting and surface distresses has been used by VDOT since 2007.
- Automated data is recognized as more objective, accurate, repeatable and safer than windshield data; however windshield rating is less expensive.
- Automated data collection also produces high quality Right of Way images which can be analyzed for data collection on other assets (such as signs or guardrail).
- Automated collection vehicles can collect additional data at the same time as the surface condition survey, such as Ground Penetrating Radar, roadway geometry or other safety related information.

Video Log Viewers

The image shows two browser windows. The top window displays a table of 'VDOT ACP Distress ratings'. A red arrow points from a 'View Vlnweb' link in the table to the URL of the bottom browser window.

Year	VDOT System ID	Route	Direction	Lane	Begin Mile	End Mile	District	County (Maint. Jurisd.)	Number of Travel Lanes	Link to External Information	Par
2010	Interstate	IS00064EB	Increasing	All	0.000	0.100	8/ST	003-Alleghany	2	View Vlnweb	BIT
2010	Interstate	IS00064EB	Increasing	All	0.100	0.200	8/ST	003-Alleghany	2	View Vlnweb	BIT

The bottom browser window shows the 'Roadware GRP - VlnWeb' interface. It features a 'QUICK Locators' sidebar with dropdown menus for District (01: BRISTOL), County (10: BLAND), RoadSystem (15), RoutelD (77N), and BeginMilePoint (C: 0.000 S: 46.680). The main area contains a video player showing a road view. The video player has a 'Locators' button on the left and a 'Video' button on the right, with standard playback controls in between.

Automated vs. Manual Data Collection

- Automated data collection has been used by MTQ since 2000 for IRI and rutting, since 2007 for cracking (fully automated 3D laser technology) and since 2011 for macrotexture (same 3D laser technology).
- For automated data collection
 - pros: objective, precise, high performance, safer for collection personnel and road users.
 - cons are: complex and expensive technology, large volume of data, limitations due to environmental conditions
- For windshield survey
 - pros: simple, allow student hiring.
 - cons: subjective, slow, risky for collection personnel and road users, data transfer required.

Scale: 1:1,691,034

Automated vs. Manual Data Collection

- NCDOT is in their first cycle of automated distress data collection.
 - Pros: More repeatable data, better coverage of key network areas. Distress and RoW imagery can be used by all DOT users. Collects multiple data sets in one pass. Potentially useful for inventory of signs and safety.
 - Cons: Large data storage needs. Expensive - either contract out collection and processing for a high rate or buy an expensive vehicle and hire additional employees to process. However, balanced against the number of personnel involved in a windshield survey, it's potentially not so bad.
- Windshield:
 - Pros: Employees that own the roads, ride the roads. They get a first hand look at conditions.
 - Cons: Slow. High variability. Safety issues. Painful data validation issues.

AGILEASSETS

Sealed Cracks in Survey

- How does the PMS address the benefits of crack treatments in the condition rating? Specifically, how does the PMS analyze crack data for treated cracks?

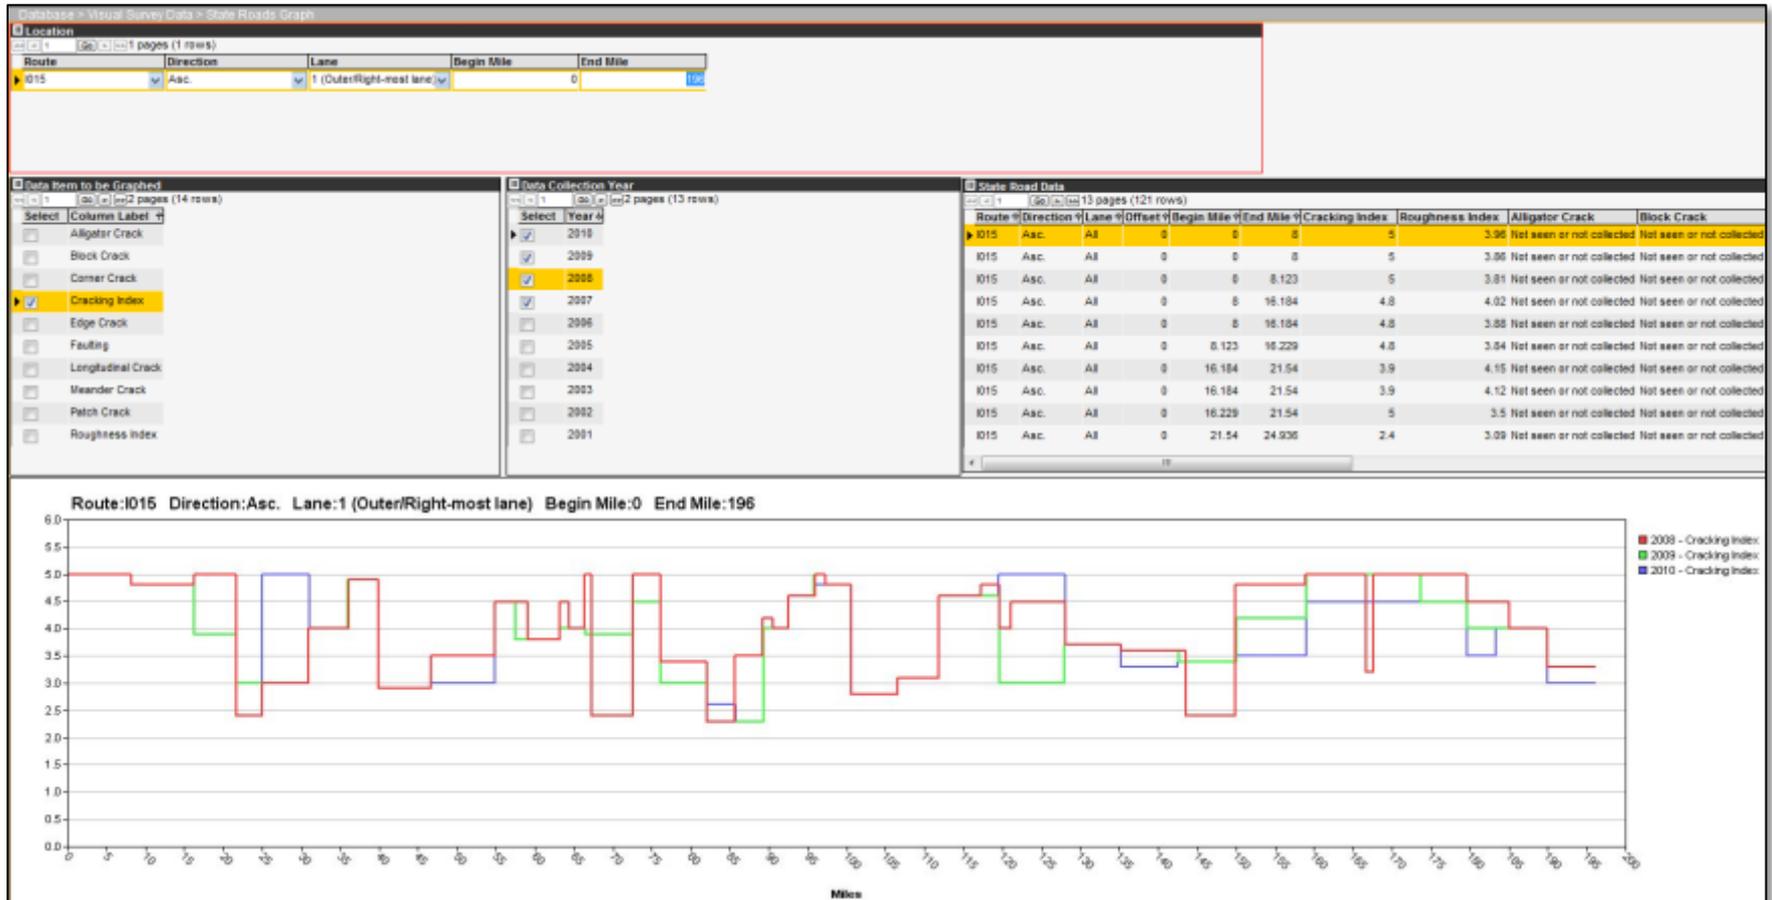

Sealed Cracks in Survey

- VDOT
 - Sealed cracks are rated as the lowest severity of cracking, this can improve the condition rating of the section.
- MTQ
 - Global cracking index: increase 70, no higher than 100
 - Transverse cracking index: increase 30, no higher than 100
 - IRI index: increase RSL by 2 years
- NCDOT
 - Sealed cracks (well sealed without significant alligator patterns) are considered low severity. Cracking indices are bumped up to the low severity level.

Comparing Condition Graphically

Data Used for PP Decisions

- What condition data do you look for to trigger a pavement preservation treatment? For certain treatments should timing be used?

Data Used for PP Decisions

- MTQ
 - Crack sealing: defined min and max cracking presence.
 - Thin overlay, micro-surfacing: age.
- VDOT
 - An extensive decision matrix is used to identify the appropriate category of maintenance activities to apply to a section. This matrix utilizes detailed distress severity/frequency information in combination with traffic, surface age and FWD information if available.

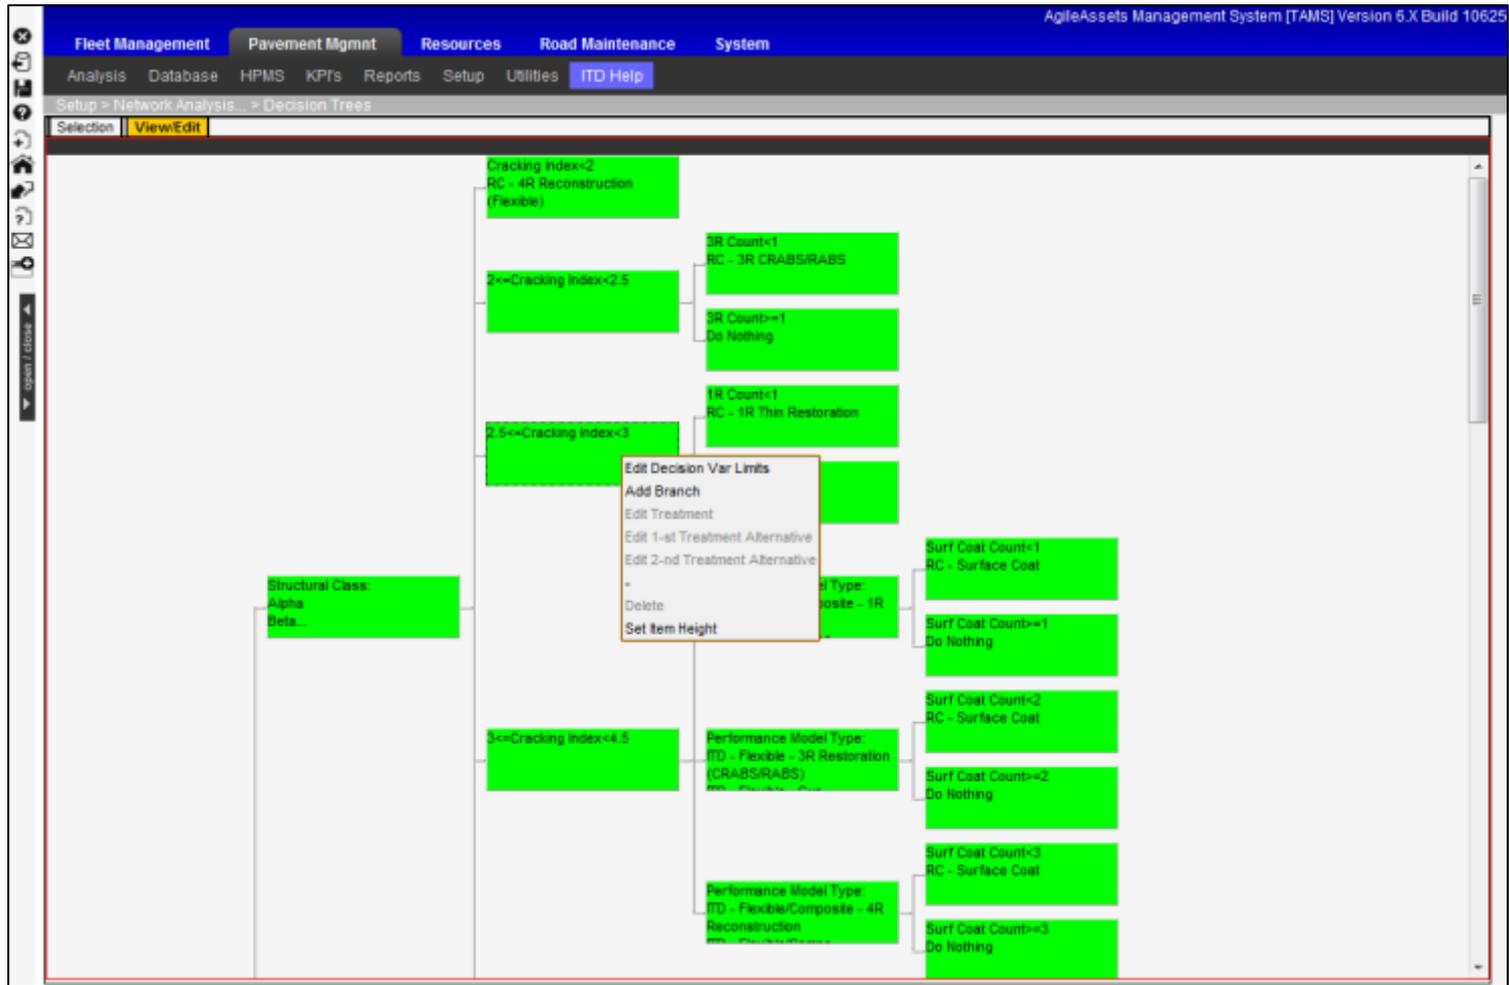

Data Used for PP Decisions

- NCDOT
 - NCDOT triggers PP treatments based on individual distresses for asphalt pavements. Cracking indices and rutting should be fair to good.
 - The overall goal is to treat when the composite rating index is 80 or higher.
 - NCDOT has found that for some activities such as chip seal programs, timing based treatments (every N years) are often more beneficial than analysis based treatments.

Modify Other Pavement Characteristics

The right treatment on the right road at the right time

- Many pavement preservation treatments are placed on roads in poor condition (as a band-aid fix). This practice can contaminate the overall treatment data. What is the best way to segregate the data in the PMS to avoid mislabeling the treatment's performance?

The right treatment on the right road at the right time - MTQ

- Specifically identify roads where a “band-aid fix” (MTQ calls it a “palliative” treatment) has been applied. A specific performance curve with a steeper slope is attached to those roads.
- At MTQ, palliative treatments are embedded in a pavement conservation strategy, where they are considered as a cheap temporary solution pending the rehabilitation treatment to be done a few years later.

The right treatment on the right road at the right time - VDOT

- VDOT is currently establishing a process to verify treatment selection against the maintenance need at the location. This process may evolve to include the development of deterioration models for “misapplied” treatments.

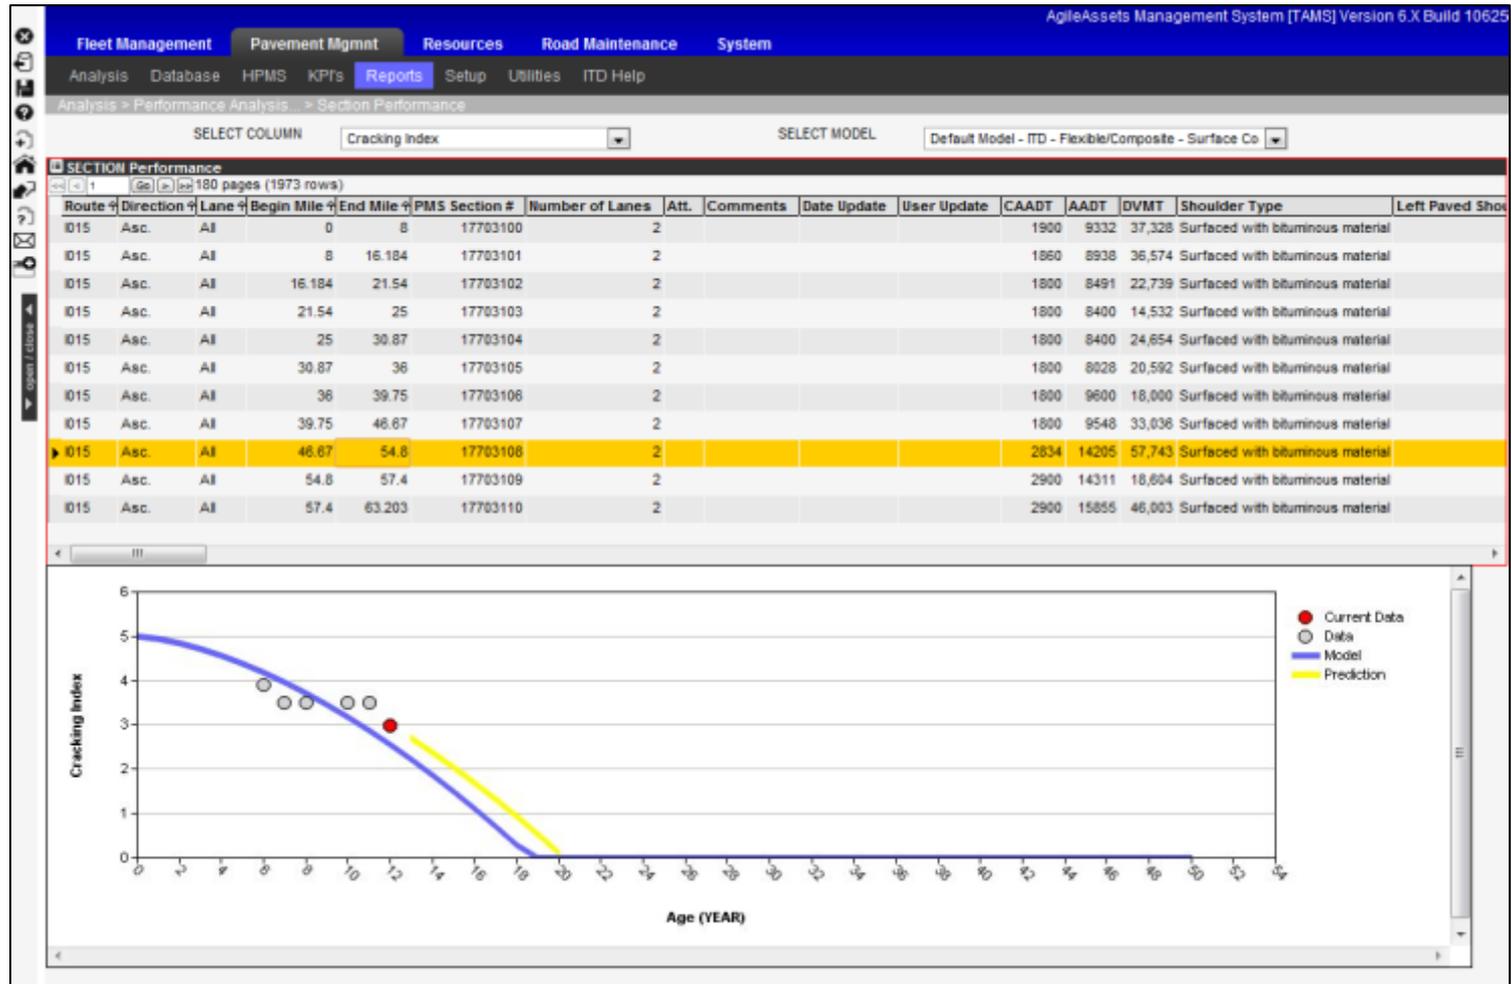

The right treatment on the right road at the right time - NCDOT

- The NCDOT models and decision trees specifically handle “band-aid fixes”. With good data, treatments will not be recommended that conflict with the condition of the road.
- NCDOT has also created a PMS report that allows anyone to look at project selection retroactively. The user can look at the most recent chip seal program and determined if good preservation guidelines were followed .
- When the integrated PMS/MMS is used for planning, they can proactively run such a report.

Section Modeling

Differentiation in Preventive Treatments

- Can pavement management models be fine tuned enough to indicate which exact preventive treatment should be applied (crack sealing vs. chip seal vs. slurry seal vs. microsurfacing, for example)?

Differentiation in Preventive Treatments

- MTQ – Can be done with a combination of models and condition indexes.
- VDOT - Current VDOT/VTTI research project is developing “fine tuned” models to incorporate in PMS to accomplish this.
- NCDOT – A judicious combination of models and decision trees makes it work. It does require vetting by various resources and getting field feedback as well. Even so, the final decision will always be a field decision for NCDOT.

How to Best Integrate PP into PMS

- Provide some pointers on how to best integrate pavement preservation into a PMS.

How to Best Integrate PP into PMS

- MTQ - Give a specific budget in the analysis (sub-constraint). At MTQ, preventive maintenance is also embedded in the pavement conservation strategy.
- NCDOT - Careful decision tree setup. Understanding the index improvement values that should be applied during analysis. Use multiple budgets.
- VDOT - Optimizations are run in the PMS to determine the ideal treatments to achieve agency established performance targets. These will include Preservation activities.

Network Analysis

Multi-Constraint Optimization

The Goal

- Best set of projects
 - The projects meet a set of constraints
 - Maximizes or minimizes an objective (Maximize condition, minimize budget, etc.)
- The desired **Output** of the analysis is a **Workplan** that tells us:
 - Which treatments to apply (What – including PP)
 - To which sections (Where)
 - In which year (When)

History

- VDOT desired multi-constraint analysis
 - Maintain certain average condition
 - No more than 18% of deficient lane mileage
 - Precluded the use of Incremental Benefit Cost methods because they can only analyze one constraint at a time
- For VDOT we developed an integer programming based optimization to allow these types of analysis

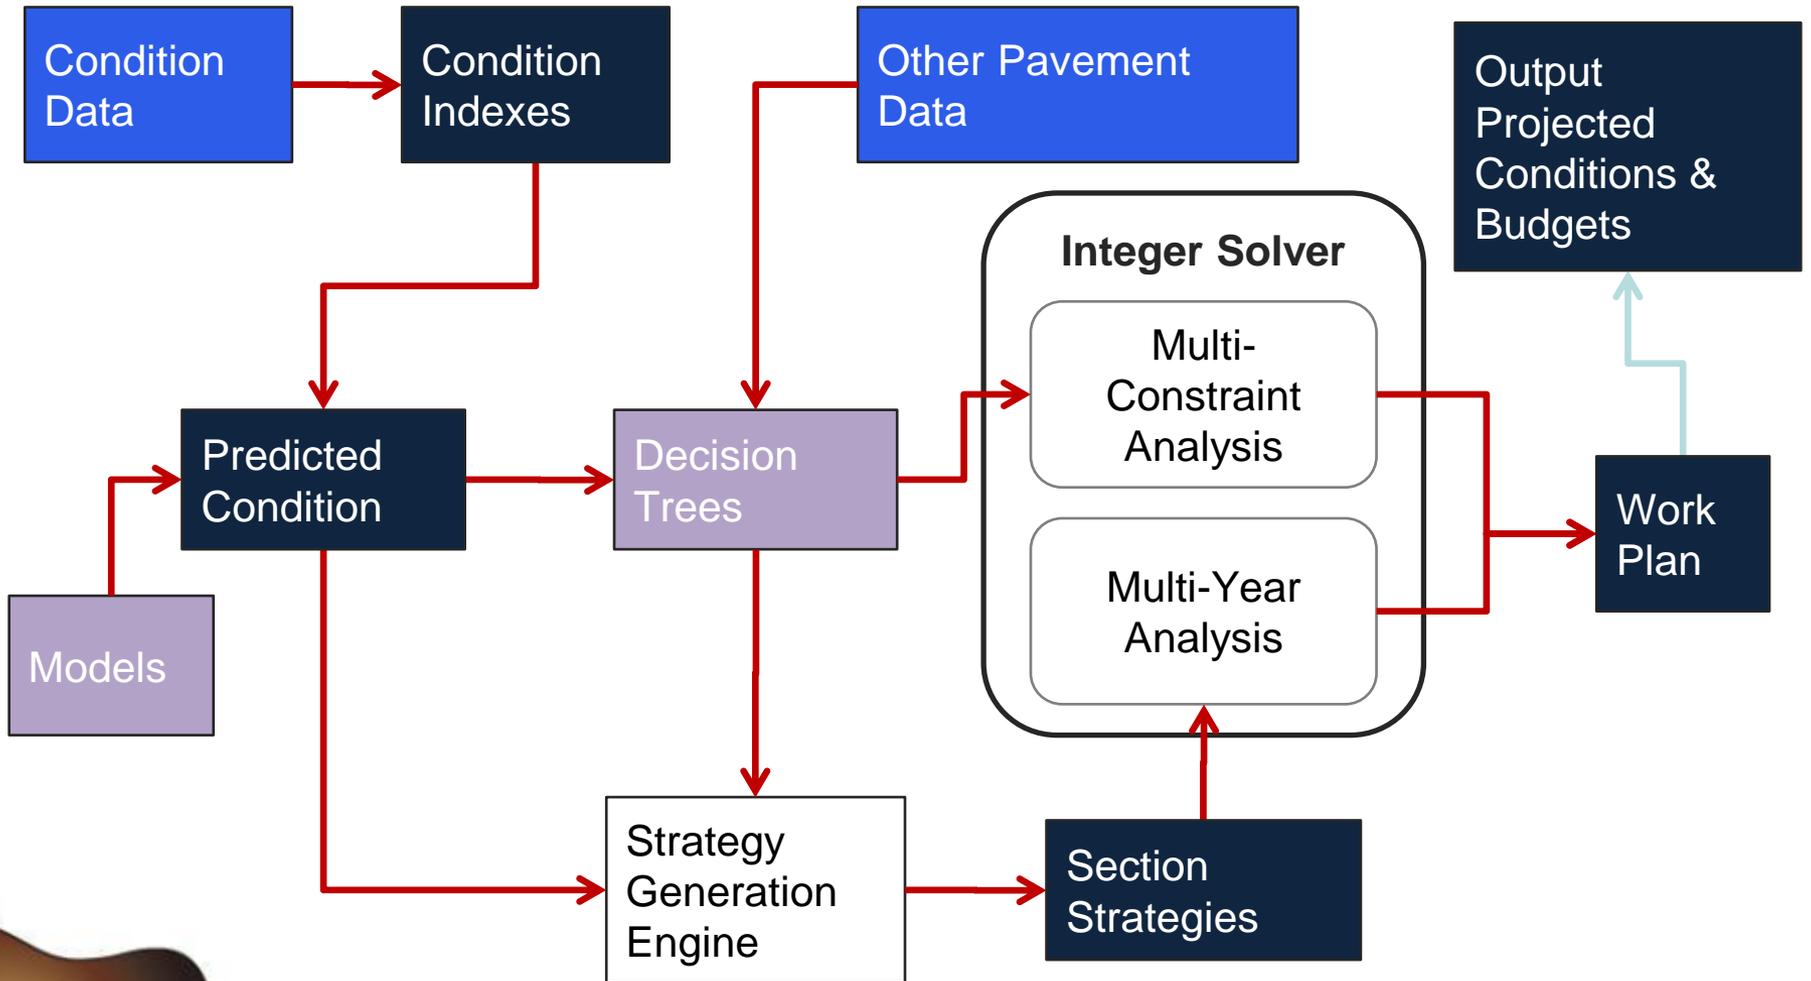

Integer Optimization Features

- State of the art Optimization analysis
 - Integer programming
 - Optimal work plans, **not** worst-first or INCBEN ranking
- Greater flexibility than prioritization and incremental benefit cost ranking methods
 - Analyze multiple constraints at once
 - Maintaining average condition **and** cap deficient mileage
 - Meet a budget constraint and limit on deficient mileage
 - Subdivide constraints within the same scenario
 - Specify minimum condition by functional class
 - Break down budgets by treatment type (Rehab, Preservation, Reconstruction)

Optimization Analysis

Predicted Condition on Maps

Advantages of Commercial PMS

- What is the advantage of a commercial PMS over an agency built system?

Advantages of Commercial PMS

- MTQ - Get an already functional PMS, benefit from the expertise of the company, benefit from the enhancements brought by other clients.
- VDOT – Same as above
- NCDOT - Numerous: We get timely service rather than relying on getting scheduled in by IT. We get unexpected enhancements due to vendor development and requests from other agencies. Historically, optimization analysis has been a thorny problem to execute gracefully and the PMS gave us a state-of-the-art capability in that area.

Thank You.
